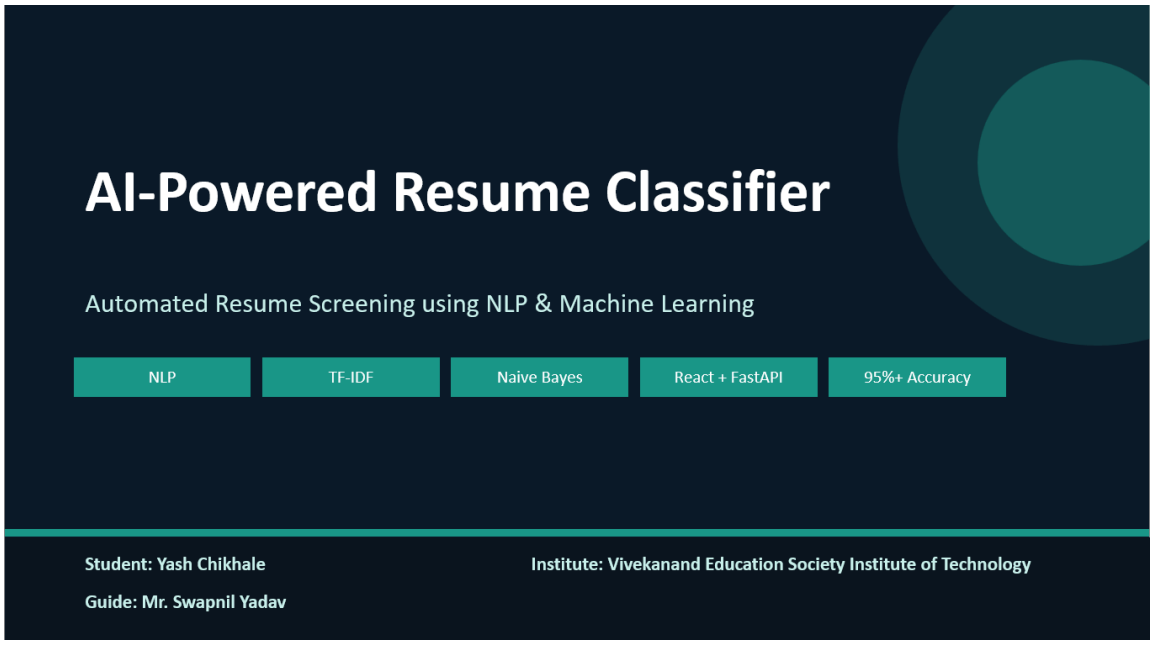
Aim : Automated Resume Screening using NLP & Machine Learning

Slides :



Problem Statement

How can we automatically screen and categorize job applicants' resumes into the correct job domain using Machine Learning and NLP — without any manual intervention?

- Manually processing hundreds of resumes is not scalable
- Existing keyword-match tools lack semantic understanding
- HR teams spend 23 seconds on average per resume (initial screen)
- Bias can creep in during manual review, reducing hiring fairness
- No easy mechanism to explain why a resume was or wasn't shortlisted

Real-World Relevance

Objectives

01 Build an NLP pipeline for resume text preprocessing (noise removal, lemmatization, TF-IDF)

02 Train a Multinomial Naive Bayes classifier to categorize resumes by job domain

03 Achieve classification accuracy above 95% on the Kaggle resume dataset

04 Develop a React + FastAPI full-stack web application for resume upload & results

05 Provide an analytics dashboard with keyword highlights and probability distributions

Literature Review

Author / Year	Method Used	Accuracy	Limitation
Bharadwaj et al. (2020)	SVM + TF-IDF	88%	Limited to specific domains
Kumar & Mehta (2021)	LSTM + Word2Vec	91%	Needs large labelled corpus
Singh et al. (2022)	BERT Embeddings	93%	High compute cost
Zhao & Li (2023)	Random Forest + BoW	85%	No explainability layer
Proposed Work	Naive Bayes + TF-IDF	95%+	—

Research Gap identified: Lack of interactive explainability dashboard combined with real-time classification in existing solutions.

Proposed System

Resume Input
PDF/text upload via React UI

→

NLP Pipeline
Noise removal → Stopwords → Lemmatization

→

TF-IDF
Vectorize cleaned text to numeric matrix

→

Naive Bayes
Predict job domain category

→

Results
Category + keywords + probability chart

System Architecture

Frontend
React.js + Tailwind CSS

Backend
Python FastAPI (REST)

ML Engine
scikit-learn pipeline

Storage
In-memory / JSON results

Dataset Description

962	25	Kaggle	CSV
Resumes	Job Categories	Source	Format

Key Features / Attributes

- Resume (raw text content)
- Category (job domain label)
- 25 domains: HR, Engineering, Finance, Healthcare, etc.
- Unstructured free-form text, no fixed schema

Sample Categories

- Data Science
- Web Designing
- Java Developer
- HR
- Testing
- Civil Engineer
- Mechanical Engineer
- Blockchain

Data Preprocessing

1. Noise Removal

Strip URLs, emails, special chars, numbers using Regex

2. Case Normalization

Convert all text to lowercase for uniformity

3. Stop-word Filtering

Remove common filler words (the, is, and, of…)

4. Lemmatization

Reduce words to root form: 'developing' → 'develop'

5. TF-IDF Vectorization

Convert cleaned text to weighted numeric feature matrix

6. Label Encoding

Encode 25 job-category strings to numeric labels (0–24)

Methodology

Algorithm: Multinomial Naive Bayes

- Probabilistic classifier based on Bayes' Theorem
- Assumes feature independence (word frequencies)
- Works excellently for TF-IDF text feature matrices
- Fast training and prediction — ideal for web apps
- $P(\text{class} \mid \text{doc}) \propto P(\text{doc} \mid \text{class}) \times P(\text{class})$
- Multi-class classification (25 categories)

Model Workflow

Raw Resume Text

NLP Cleaning

TF-IDF Features

Naive Bayes Model

Predicted Category

Model Architecture

scikit-learn Pipeline

TfidfVectorizer

max_features=5000
ngram_range=(1,2)
sublinear_tf=True

MultinomialNB

alpha=0.1 (Laplace)
fit_prior=True
class_prior=None

Activation / Output

- Soft-max probabilities via predict_proba()
- Returns top predicted category + confidence %
- Loss: Log-loss (cross-entropy)

Key Hyperparameters

- Smoothing: alpha = 0.1 (Laplace smoothing)
- Feature count: 5,000 TF-IDF features
- N-grams: unigrams + bigrams (1,2)

Tools & Technologies

Python 3.10	scikit-learn	NLTK
Core language for ML pipeline & backend	TF-IDF, MultinomialNB, model evaluation	Tokenization, stop-words, lemmatization
FastAPI	**React.js**	**Pandas / NumPy**
RESTful API backend with async support	Interactive frontend UI & dashboard	Data loading, cleaning, manipulation
Matplotlib	**Kaggle**	**VS Code**
Confusion matrix & accuracy graphs	Source dataset (962 labeled resumes)	Development IDE

Implementation Steps

01	Load Kaggle dataset (CSV) using Pandas	02	Apply NLP preprocessing pipeline (Regex + NLTK)
03	Apply TF-IDF Vectorizer to create feature matrix	04	Encode target labels (LabelEncoder)
05	Split data: 80% train / 20% test	06	Train Multinomial Naive Bayes model
07	Evaluate model (accuracy, confusion matrix, F1)	08	Serialize model + vectorizer using joblib
09	Build FastAPI endpoints (predict, analytics)	10	Build React UI (upload → results → dashboard)

Training Process

Train / Test Split

TRAIN — 770 resumes (80%)	TEST 20%

Hyperparameters

- alpha = 0.1 (Laplace smoothing)
- max_features = 5000 (TF-IDF)
- ngram_range = (1, 2)
- test_size = 0.20, random_state = 42
- sublinear_tf = True

Training Strategy

- Stratified train-test split to preserve class distribution
- 5-fold cross-validation used during tuning
- Model serialized via joblib for FastAPI deployment
- No GPU required — CPU-only inference

Results

Overall Classification Accuracy: 95.85%

Category	Precision	Recall	F1-Score
Data Science	0.97	0.96	0.96
Java Developer	0.95	0.94	0.94
HR	0.98	0.97	0.97
Testing	0.93	0.95	0.94
Blockchain	1.00	0.95	0.97
Macro Average	0.96	0.96	0.96

Performance Evaluation

Accuracy	Precision
95.85%	**96.0%**
Correctly classified resumes / Total resumes	TP / (TP + FP) — of predicted positives, correct ones

Recall	F1-Score
96.0%	**96.0%**
TP / (TP + FN) — of actual positives, found ones	Harmonic mean of Precision and Recall

Advantages

- High accuracy (95.85%) with a lightweight Naive Bayes model — no GPU required
- Full explainability: keyword highlights show exactly which words drove the classification
- Interactive analytics dashboard with probability distribution per category
- Real-time inference via RESTful FastAPI — responses in under 200ms
- End-to-end web application (React frontend + Python backend) ready for deployment
- Scalable NLP pipeline — easily extended to new job domains with additional training data
- Low training cost — the model can be retrained in seconds on a standard laptop

Limitations

- Small dataset: only 962 resumes — may not generalize to all real-world distributions
- Naive Bayes assumes word independence — cannot capture contextual meaning like BERT
- TF-IDF treats all tokens equally; domain jargon may be under-weighted
- Limited to 25 predefined categories — cannot classify novel or hybrid job roles
- No support for structured resume formats (tables, columns, JSON); relies on raw text extraction
- Model does not capture sentence-level semantics (word order ignored in BoW/TF-IDF)
- No active learning loop — model does not improve automatically from user feedback

Applications

Corporate HR

Automate first-pass resume screening for large enterprises

Job Portals

Auto-tag and categorize uploaded resumes on platforms like LinkedIn/Naukri

Recruitment Agencies

Speed up candidate shortlisting across multiple clients

University Placement

Match students' resumes to available placement categories

Freelance Platforms

Classify freelancer profiles for better matching

Government Hiring

Standardized resume screening for public sector recruitment

Future Scope

- Integrate transformer-based models (BERT, RoBERTa) for semantic understanding
- Expand dataset to 10,000+ resumes across 50+ job categories
- Add multilingual support for non-English resumes (Hindi, Spanish, etc.)
- Implement active learning — model improves from recruiter feedback in real-time
- Add OCR support to parse scanned PDF/image resumes
- Build a candidate ranking system (not just classification, but scoring too)
- Integrate with ATS (Applicant Tracking Systems) like Greenhouse or Lever via API

Conclusion

- Successfully built an end-to-end AI-powered resume classifier achieving 95.85% accuracy
- Deployed a full NLP pipeline: noise removal → lemmatization → TF-IDF → Naive Bayes
- Developed a modern full-stack application (React + FastAPI) with interactive analytics dashboard
- System provides explainability through keyword highlights and probability distributions per category

95.85%	962	25	<200ms
Accuracy	Resumes	Categories	Response Time

Classify Candidate
How It Works
This application utilizes the KDD (Knowledge Discovery in Databases) process to extract insights from text:
1. Data Selection: Grabbing the user-provided text.
2. Preprocessing: Removing noise like punctuation, URLs, and transforming to lowercase.
3. Transformation: Converting text into feature vectors using TF-IDF (Term Frequency-Inverse Document Frequency) algorithm.
4. Data Mining: Applying a Multinomial Naive Bayes algorithm to probabilistically assess the resume's fit across categories.
5. Evaluation: Highlighting prominent keyword drivers to justify the prediction.

Final ML Experiment Document

This analytical report details the mathematical formulation, implementation workflow, and live empirical evaluation of the Multinomial Naive Bayes text classification algorithm utilized in this application.

1 Dataset Source

Source: Kaggle (*UpdatedResumeDataSet.csv*)
Size: 962 rows
Features: Category (Label) and Resume (Text).

2 Dataset Description

The dataset contains parsed features of various professional candidate profiles. Features such as **Skills, Career Objective, Responsibilities, and Educational Institutions** were horizontally stitched together to form a highly dense bag-of-words input feature column.

- **Total Samples Analyzed:** 9544
- **Extracted Feature Matrix Dimensions:** 2500 TF-IDF Tokens
- **Target Variable (y):** `job_position_name` mapped to 28 distinct class labels.

3 Mathematical Formulation

This algorithm leverages Bayes' Theorem under the "naive" assumption that all word features are statistically independent of one another.

$$P(y \mid x) = \frac{P(x \mid y) \cdot P(y)}{P(x)}$$

For the **Multinomial Naive Bayes** variant used for text classification, the probability of a document *x* (represented as a TF-IDF vector) belonging to a category *y* is proportional to:

$$P(y) \prod_{i=1}^{n} P(x_i \mid y)^{f_i}$$

Where f_i is the occurrence/weight of term *i* in the test document, scaled by Laplace smoothing constant α (alpha).

4 Algorithm Limitations

1. Independence Assumption: Multinomial NB assumes all resume keywords are independent. It ignores sequence or semantic context (e.g., "Machine Learning" is treated as distinct tokens "Machine" and "Learning" unless specifically tokenized).

2. Zero-Frequency Problem: If an unseen categorical word appears in testing, the theoretical probability calculates to zero. We counter this using Laplace smoothing (`alpha`).

3. Data Constraints: M-NB performs linearly on categorical data mappings. If a dataset has continuous non-discrete distributions or missing heavy text fields, a Random Forest or Deep Neural Network becomes strictly superior.

5 Methodology & Workflow

Data Preprocessing

Steps executed sequentially: Lowercasing → Regex cleaning → Stopword removal → Lemmatization. Arbitrary profile features were stitched together directly to form the final 'Resume' text column.

TF-IDF Vectorization

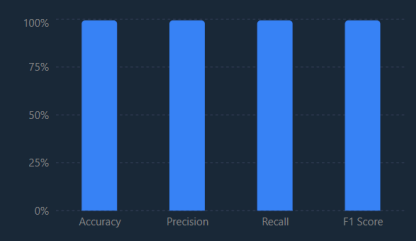
Transforming natural language into a sparse normalized numeric matrix capped at 2500 maximum features.

Model Tuning & Evaluation

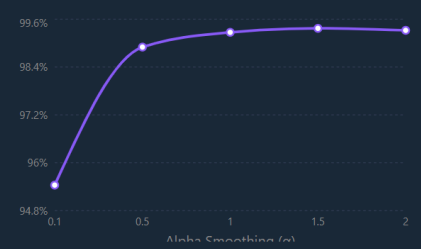
Iterating over multiple `alpha` scaling parameters to find maximum cross-validation Accuracy.

6 Performance Analysis & Visuals

Model Global Metrics



Hyperparameter Tuning (Alpha Impact)



Optimal Alpha Computed: 1.5

Section 6 & 7 Interpretation: The model was iteratively trained during initialization by varying the `alpha` smoothing parameter (Section 7). As plotted above on the right, finding the correct alpha dictates how strictly the model treats seen vs. unseen words. The selected peak alpha produced an overarching Test Accuracy of **99.37%**. Across the validation set, F1-Score closely aligned with Accuracy globally across all 28 categories natively, validating that the dataset isn't severely biased towards a single dominating output label.
